Key Anatomical Landmarks of the Buttocks

The surface anatomy of the buttocks is defined by several palpable and visible landmarks that help in orientation and clinical examination. These landmarks serve as reference points for locating underlying structures and for performing medical procedures safely.

Posterior Superior Iliac Spine (PSIS)

The posterior superior iliac spine is a prominent bony projection of the iliac crest and is easily palpable. It is located at the upper border of the buttocks near the midline and often corresponds externally to the dimples sometimes visible on the lower back. The PSIS serves as an important landmark for identifying the sacroiliac joint and demarcating the upper boundary of the buttocks.

Gluteal Fold

The gluteal fold is the horizontal crease at the inferior aspect of the buttocks where the buttocks meet the posterior thigh. This fold is significant as it demarcates the lower

boundary of the gluteal region and is a useful landmark for intramuscular injections and clinical inspection.

Greater Trochanter of the Femur

The greater trochanter is a large, palpable bony prominence on the lateral aspect of the proximal femur. It lies inferior and lateral to the buttocks and serves as a critical landmark for muscle attachment sites and for locating the safe region for gluteal injections.

Intergluteal Cleft

The intergluteal cleft, commonly called the natal cleft or buttock crease, is the vertical groove that separates the two buttocks. This surface feature is notable for its role in hygiene, clinical examination, and as a guide in certain surgical approaches.

- Posterior Superior Iliac Spine (PSIS)
- Gluteal Fold
- Greater Trochanter of the Femur
- Intergluteal Cleft

Musculature of the Buttocks Region

The surface anatomy of buttocks is largely influenced by the underlying musculature which shapes the contour and provides functional capabilities such as hip extension, abduction, and rotation. The primary muscles in this region include the gluteus maximus, gluteus medius, and gluteus minimus.

Gluteus Maximus

The gluteus maximus is the largest and most superficial muscle of the buttocks. It originates from the posterior ilium, sacrum, and coccyx and inserts into the iliotibial tract and the gluteal tuberosity of the femur. This muscle is responsible for powerful hip extension and external rotation. The bulk of the gluteus maximus forms the visible mass of the buttocks and is a key surface anatomy feature.

Gluteus Medius and Minimus

Located deep to the gluteus maximus, the gluteus medius and minimus muscles originate from the ilium and insert onto the greater trochanter of the femur. These muscles play

critical roles in hip abduction and stabilization during gait. Their outline is less visible but can be appreciated through surface landmarks and muscle testing.

Other Muscles Affecting Buttock Contour

Several smaller muscles contribute to the buttocks' shape and function, including the piriformis, tensor fasciae latae, and the deep lateral rotators. These muscles assist in hip rotation and provide additional contour to the lateral and inferior aspects of the buttocks.

- Gluteus Maximus – largest, superficial muscle forming the buttock shape
- Gluteus Medius – deeper, responsible for hip abduction
- Gluteus Minimus – smallest, deep muscle aiding in hip stabilization
- Piriformis and other lateral rotators – assist in hip rotation and contour

Vascular Supply and Innervation

The surface anatomy of the buttocks is closely related to the vascular and nervous structures that supply the skin, muscles, and deeper tissues. Knowledge of these structures is essential for surgical interventions and avoiding complications.

Arterial Supply

The primary arterial supply to the buttocks originates from the superior and inferior gluteal arteries, branches of the internal iliac artery. The superior gluteal artery exits the pelvis through the greater sciatic foramen above the piriformis muscle, supplying the gluteus medius and minimus. The inferior gluteal artery exits below the piriformis and supplies the gluteus maximus and adjacent muscles. These arteries create an extensive vascular network supporting the buttock tissues.

Venous Drainage

Venous return from the buttocks parallels the arterial supply, with the superior and inferior gluteal veins draining into the internal iliac vein. The venous plexus in this region helps regulate blood flow and temperature of the gluteal tissues.

Nervous Innervation

The cutaneous and muscular innervation of the buttocks is primarily provided by the superior and inferior gluteal nerves, branches of the sacral plexus. The superior gluteal

nerve innervates the gluteus medius, minimus, and tensor fasciae latae, while the inferior gluteal nerve supplies the gluteus maximus. Additionally, the sciatic nerve passes deep to the gluteus maximus and provides motor and sensory innervation to the lower limb. Several smaller cutaneous nerves supply the skin over the buttocks, including the posterior femoral cutaneous nerve.

- Superior Gluteal Artery and Nerve
- Inferior Gluteal Artery and Nerve
- Venous Drainage via Gluteal Veins
- Sciatic Nerve Passage
- Cutaneous Innervation by Posterior Femoral Cutaneous Nerve

Surface Topography and Clinical Significance

The surface anatomy of buttocks is crucial for clinical evaluation, particularly for safe administration of intramuscular injections, assessment of trauma, and surgical planning. Recognizing the surface landmarks and underlying structures minimizes risks and improves diagnostic accuracy.

Intramuscular Injection Sites

The upper outer quadrant of the buttocks is the recommended site for intramuscular injections to avoid injury to the sciatic nerve and major blood vessels. This area corresponds roughly to the region over the gluteus medius muscle, lateral to the intergluteal cleft and superior to the gluteal fold.

Palpation and Physical Examination

Palpation of the posterior superior iliac spine, sacrum, and greater trochanter assists in identifying abnormal bony prominences or asymmetry. Evaluation of muscle bulk and tone can provide information about neuromuscular disorders affecting the lower limb and pelvis.

Surgical and Diagnostic Considerations

Surgeons rely on surface anatomy of the buttocks to plan approaches for hip replacement, abscess drainage, and cosmetic procedures such as gluteal augmentation. Imaging techniques correlate surface landmarks with internal anatomy to enhance precision.

- Safe Zones for Intramuscular Injections
- Palpation of Bony and Muscular Landmarks
- Assessment of Muscle Bulk and Symmetry
- Surgical Planning and Imaging Correlation

Common Anatomical Variations and Considerations

An understanding of common anatomical variations in the surface anatomy of buttocks is important for clinicians to avoid diagnostic errors and procedural complications. Variations may affect muscle size, fat distribution, and vascular patterns.

Variations in Muscle Bulk

Muscle hypertrophy or atrophy can alter the contour of the buttocks. Athletic individuals often have pronounced gluteus maximus muscles, while sedentary or elderly individuals may exhibit reduced muscle mass, affecting palpation and visualization of landmarks.

Fat Distribution and Surface Contour

Adipose tissue distribution varies widely among individuals, influenced by genetics, sex, and age. This variability affects the appearance of the gluteal region, sometimes obscuring underlying landmarks and complicating clinical assessment.

Vascular and Nervous Variations

Occasional anatomical differences in the course of the superior and inferior gluteal vessels or nerves may increase the risk of inadvertent injury during procedures. Awareness of these variations supports safer clinical practice.

- Muscle Bulk Variations due to Hypertrophy or Atrophy
- Differences in Adipose Tissue Distribution
- Anomalies in Vascular and Nervous Anatomy
- Impact on Clinical and Surgical Procedures
