Understanding the System of Equations Elimination Method

The elimination method is a powerful algebraic technique used to solve systems of linear equations by removing one variable through addition or subtraction of equations. This approach contrasts with substitution, focusing on combining equations to isolate and solve for variables systematically. A system of equations typically involves two or more equations with two or more variables, and the goal is to identify the values that satisfy all equations simultaneously.

Definition and Purpose

The elimination method involves manipulating the system so that adding or subtracting the equations cancels out one variable, leaving a single-variable equation that can be solved directly. This method is particularly useful when the coefficients of one variable are opposites or can be made opposites by multiplication. The purpose is to simplify complex systems into manageable equations to find precise solutions.

Step-by-Step Process

The elimination method follows a clear sequence of steps:

1. Arrange the system of equations in standard form ($Ax + By = C$).
2. Multiply one or both equations by constants to align coefficients of a variable.
3. Add or subtract the equations to eliminate one variable.
4. Solve the resulting single-variable equation.
5. Substitute the solution back into one of the original equations to find the other variable.
6. Verify the solution by plugging both values into the original equations.

Sample Problem 1: Basic Elimination

Solve the system:

1. $2x + 3y = 8$

2. $4x - 3y = 2$

Solution involves adding the two equations to eliminate y , then solving for x , followed by substitution to find y .

Sample Problem 2: Multiplying to Align Coefficients

Solve the system:

1. $3x + 2y = 16$

2. $5x + 7y = 31$

Multiply equations to create opposite coefficients for y or x , then add or subtract to eliminate one variable.

Practice Strategies
